Introduction

Project background and context

SpaceX offers Falcon 9 rocket launches for \$62 million on its website, while other companies charge over \$165 million per launch. The main reason for this price difference is that SpaceX can reuse the first stage of its rockets. So, if we can predict whether the first stage will land successfully, we can estimate the cost of a launch. This prediction can be valuable for other companies competing with SpaceX for rocket launch contracts. The project aims to develop a machine learning system to forecast the success of the first stage landing.

Problems you want to find answers

- What factors determine if the rocket will land successfully?
- The interaction amongst various features that determine the success rate of a successful landing.
- What operating conditions needs to be in place to ensure a successful landing program.

Methodology

Executive Summary

- Data collection methodology:
 - Data was collected using SpaceX API and web scraping from Wikipedia.
- Perform data wrangling
 - One-hot encoding was applied to categorical features.
- Perform exploratory data analysis (EDA) using visualization and SQL
- Perform interactive visual analytics using Folium and Plotly Dash
- Perform predictive analysis using classification models
 - How to build, tune, evaluate classification models

Data Collection

- The data was collected using various methods
 - Data collection was done using get request to the SpaceX API.
 - Next, we decoded the response content as a Json using .json() function call and turn it into a pandas dataframe using .json_normalize().
 - Next, we tidied up the data, making sure there were no gaps and filling in any missing information as needed.
 - Additionally, we utilized web scraping techniques using BeautifulSoup to gather Falcon 9 launch data from Wikipedia.
 - Our aim was to extract the launch records presented as an HTML table, then parse and convert this table into a pandas dataframe for further examination and analysis.

Data Collection - SpaceX API

- We employed a 'get' request to access the SpaceX API and gather data. After retrieving the data, we refined it by removing any inconsistencies and performed some fundamental data organization and formatting to ensure its usability.
- The link to the notebook is https://github.com/Ave-Avertino/Coursera-Data-Science/blob/main/SpaceX-Data%20Collection%20API.ipy nb

```
1. Get request for rocket launch data using API
       spacex url="https://api.spacexdata.com/v4/launches/past"
       response = requests.get(spacex url)
Use json_normalize method to convert json result to dataframe.
       # Use json normalize method to convert the json result into a dataframe
       # decode response content as json
       static_json_df = res.json()
       # apply json normalize
       data = pd.json normalize(static json df)
3. We then performed data cleaning and filling in the missing values
       rows = data falcon9['PayloadMass'].values.tolist()[0]
       df_rows = pd.DataFrame(rows)
       df rows = df rows.replace(np.nan, PayloadMass)
       data_falcon9['PayloadMass'][0] = df_rows.values
       data falcon9
```

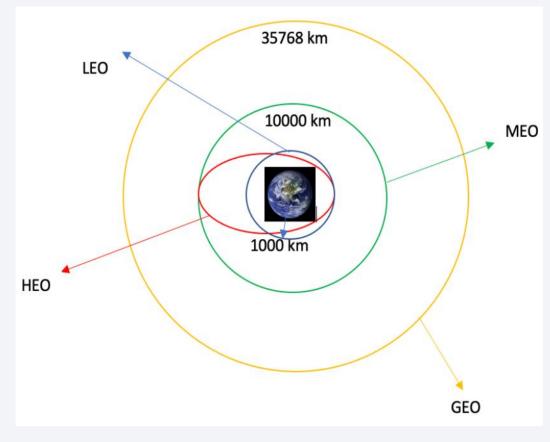

Data Collection - Scraping

- We applied web scrapping to webscrap Falcon 9 launch records with BeautifulSoup
- We parsed the table and converted it into a pandas dataframe.
- The link to the notebook is https://github.com/Ave-Avertino/Coursera-Data-Science/blob/main/SpaceX-Data%20Collection%20with%20We b%20Scraping.ipynb

```
    Apply HTTP Get method to request the Falcon 9 rocket launch page

        static_url = "https://en.wikipedia.org/w/index.php?title=List_of_Falcon_9 and Falcon Heavy launches&oldid=1027686922"
          # use requests.get() method with the provided static url
           # assign the response to a object
           html data = requests.get(static url)
          html data.status code
Out[5]: 200
    2. Create a BeautifulSoup object from the HTML response
           # Use BeautifulSoup() to create a BeautifulSoup object from a response text content
           soup = BeautifulSoup(html data.text, 'html.parser')
         Print the page title to verify if the BeautifulSoup object was created properly
           # Use soup.title attribute
           soup.title
          <title>List of Falcon 9 and Falcon Heavy launches - Wikipedia</title>
        Extract all column names from the HTML table header
          column_names = []
          # Apply find_all() function with "th" element on first_launch_table
          # Iterate each th element and apply the provided extract_column from header() to get a column name
          # Append the Non-empty column name ('if name is not None and Len(name) > \theta') into a list called column names
          for row in range(len(element)):
                 name = extract_column_from_header(element[row])
                 if (name is not None and len(name) > 0):
                     column_names.append(name)
    4. Create a dataframe by parsing the launch HTML tables
        Export data to csv
```

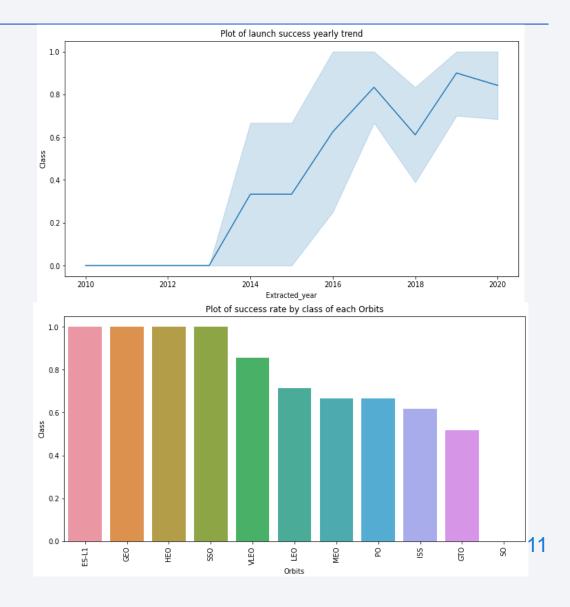

Data Wrangling

- We performed exploratory data analysis and determined the training labels.
- We calculated the number of launches at each site, and the number and occurrence of each orbits
- We created landing outcome label from outcome column and exported the results to csv.
- The link to the notebook is https://github.com/Ave-Avertino/Coursera-Data-Science/blob/main/SpaceX-Data%20Wrangling.ipynb

EDA with Data Visualization

- We delved into the data by creating visual representations of various relationships.
 These included examining the connection between flight number and launch site, payload and launch site, the success rate corresponding to each orbit type, the relationship between flight number and orbit type, as well as observing the yearly trend in launch success.
- The link to the notebook is https://github.com/Ave-Avertino/Coursera-Data-Science/blob/main/SpaceX-EDA%20with%20Data%20Visualization.i pynb

EDA with **SQL**

- We loaded the SpaceX dataset into a PostgreSQL database without leaving the jupyter notebook.
- We applied EDA with SQL to get insight from the data. We wrote queries to find out for instance:
 - The names of unique launch sites in the space mission.
 - The total payload mass carried by boosters launched by NASA (CRS)
 - The average payload mass carried by booster version F9 v1.1
 - The total number of successful and failure mission outcomes
 - The failed landing outcomes in drone ship, their booster version and launch site names.
- The link to the notebook is https://github.com/Ave-Avertino/Coursera-Data-Science/blob/main/SpaceX-EDA%20with%20SQL.ipynb

Build an Interactive Map with Folium

- We marked all launch sites, and added map objects such as markers, circles, lines to mark the success or failure of launches for each site on the folium map.
- We assigned the feature launch outcomes (failure or success) to class 0 and
 1.i.e., 0 for failure, and 1 for success.
- Using the color-labeled marker clusters, we identified which launch sites have relatively high success rate.
- We calculated the distances between a launch site to its proximities. We answered some question for instance:
 - Are launch sites near railways, highways and coastlines.
 - Do launch sites keep certain distance away from cities.

Build a Dashboard with Plotly Dash

- We built an interactive dashboard with Plotly dash
- We plotted pie charts showing the total launches by a certain sites
- We plotted scatter graph showing the relationship with Outcome and Payload Mass (Kg) for the different booster version.
- The link to the notebook is https://github.com/Ave-Avertino/Coursera-Data-Science/blob/main/app.py

Predictive Analysis (Classification)

- We loaded the data using numpy and pandas, transformed the data, split our data into training and testing.
- We built different machine learning models and tune different hyperparameters using GridSearchCV.
- We used accuracy as the metric for our model, improved the model using feature engineering and algorithm tuning.
- We found the best performing classification model.
- The link to the notebook is https://github.com/Ave-Avertino/Coursera-Data-
 - Science/blob/main/SpaceX_Machine_Learning_Prediction.ipynb

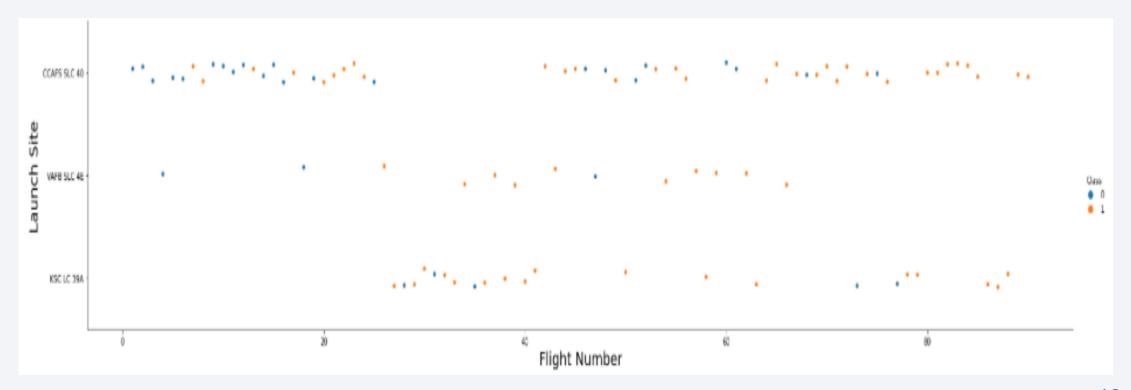

Results

- Exploratory data analysis results
- Interactive analytics demo in screenshots
- Predictive analysis results

Flight Number vs. Launch Site

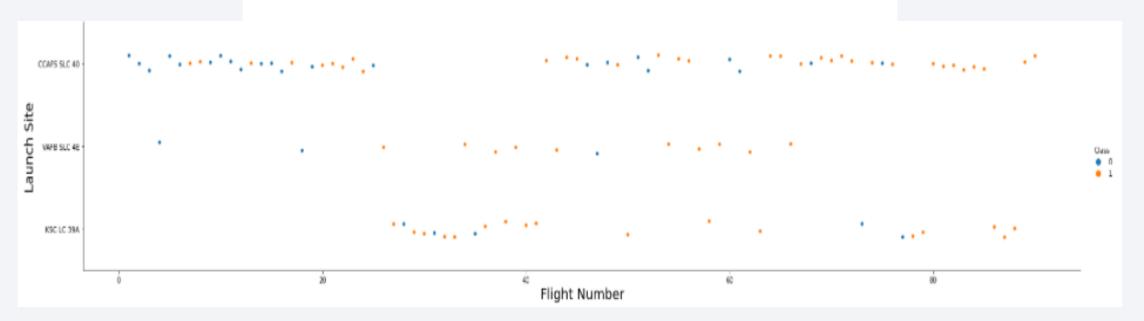

• From the plot, we found that the larger the flight amount at a launch site, the greater the success rate at a launch site.

Payload vs. Launch Site

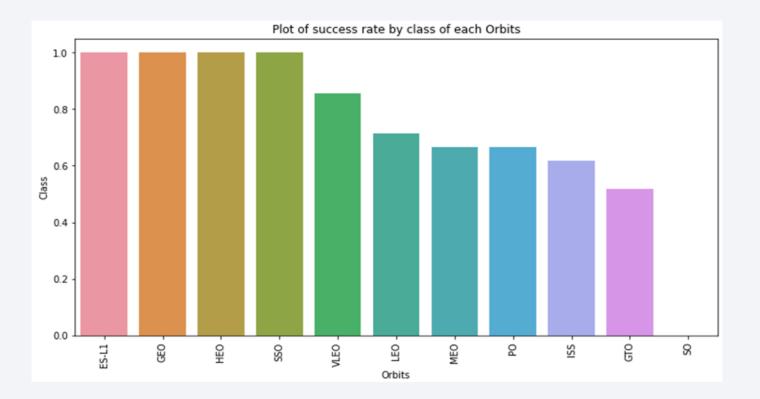

The greater the payload mass for launch site CCAFS SLC 40 the higher the success rate for the rocket.

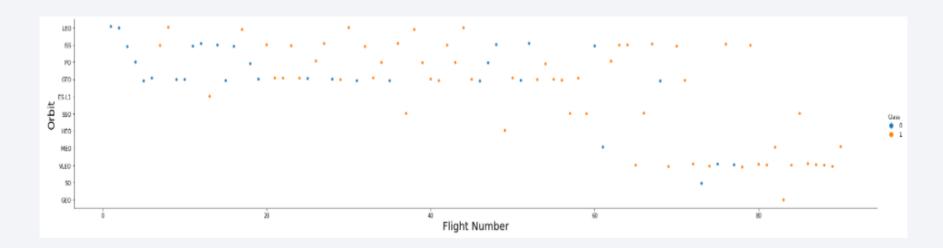

Success Rate vs. Orbit Type

 From the plot, we can see that ES-L1, GEO, HEO, SSO, VLEO had the most success rate.

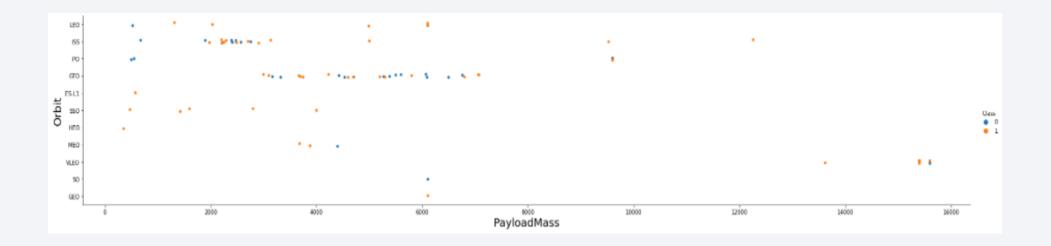

Flight Number vs. Orbit Type

 The plot below shows the Flight Number vs. Orbit type. We observe that in the LEO orbit, success is related to the number of flights whereas in the GTO orbit, there is no relationship between flight number and the orbit.

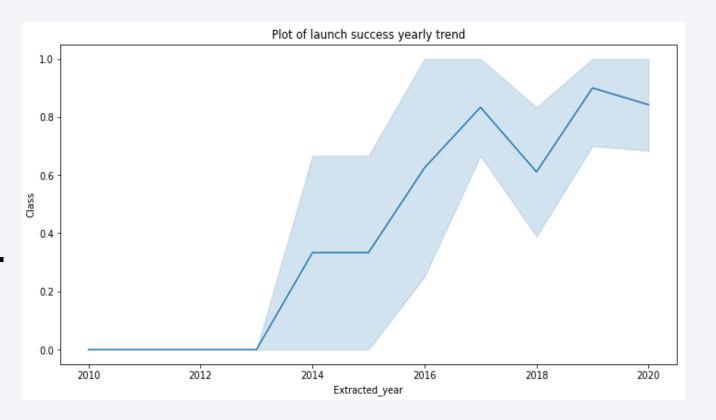

Payload vs. Orbit Type

 We can observe that with heavy payloads, the successful landing are more for PO, LEO and ISS orbits.

Launch Success Yearly Trend

 From the plot, we can observe that success rate since 2013 kept on increasing till 2020.

All Launch Site Names

 We used the key word **DISTINCT** to show only unique launch sites from the SpaceX data.

```
Display the names of the unique launch sites in the space mission
In [10]:
           task 1 = '''
                   SELECT DISTINCT LaunchSite
                   FROM SpaceX
           create pandas df(task 1, database=conn)
Out[10]:
               launchsite
              KSC LC-39A
              CCAFS LC-40
          2 CCAFS SLC-40
          3 VAFB SLC-4E
```

Launch Site Names Begin with 'CCA'

 We used the query above to display 5 records where launch sites begin with `CCA`

	Disp	lay 5 recor	ds where	launch sites be	gin with the s	tring 'CCA'					
In [11]:		FROM WHEF LIMI	ECT * 1 SpaceX RE Launcl IT 5	nSite LIKE 'CCA							
Out[11]:		date	time	boosterversion	launchsite	payload	payloadmasskg	orbit	customer	missionoutcome	landingoutcome
	0	2010-04- 06	18:45:00	F9 v1.0 B0003	CCAFS LC- 40	Dragon Spacecraft Qualification Unit	0	LEO	SpaceX	Success	Failure (parachute)
	1	2010-08- 12	15:43:00	F9 v1.0 B0004	CCAFS LC- 40	Dragon demo flight C1, two CubeSats, barrel of	0	LEO (ISS)	NASA (COTS) NRO	Success	Failure (parachute)
	2	2012-05- 22	07:44:00	F9 v1.0 B0005	CCAFS LC- 40	Dragon demo flight C2	525	LEO (ISS)	NASA (COTS)	Success	No attempt
	3	2012-08- 10	00:35:00	F9 v1.0 B0006	CCAFS LC- 40	SpaceX CRS-1	500	LEO (ISS)	NASA (CRS)	Success	No attempt
	4	2013-01- 03	15:10:00	F9 v1.0 B0007	CCAFS LC- 40	SpaceX CRS-2	677	LEO (ISS)	NASA (CRS)	Success	No attempt

Total Payload Mass

 We calculated the total payload carried by boosters from NASA as 45596 using the query below

```
Display the total payload mass carried by boosters launched by NASA (CRS)

In [12]:

task_3 = '''

SELECT SUM(PayloadMassKG) AS Total_PayloadMass
FROM SpaceX
WHERE Customer LIKE 'NASA (CRS)'

"""

create_pandas_df(task_3, database=conn)

Out[12]:

total_payloadmass

0 45596
```

Average Payload Mass by F9 v1.1

 We calculated the average payload mass carried by booster version F9 v1.1 as 2928.4

```
Display average payload mass carried by booster version F9 v1.1

In [13]:

task_4 = '''

SELECT AVG(PayloadMassKG) AS Avg_PayloadMass
FROM SpaceX
WHERE BoosterVersion = 'F9 v1.1'

create_pandas_df(task_4, database=conn)

Out[13]:

avg_payloadmass

0 2928.4
```

First Successful Ground Landing Date

 We observed that the dates of the first successful landing outcome on ground pad was December, 22 2015

Successful Drone Ship Landing with Payload between 4000 and 6000

 We used the WHERE clause to filter for boosters which have successfully landed on drone ship and applied the AND condition to determine successful landing with payload mass greater than 4000 but less than 6000

```
In [15]:
          task 6 = '''
                   SELECT BoosterVersion
                   FROM SpaceX
                   WHERE LandingOutcome = 'Success (drone ship)'
                        AND PayloadMassKG > 4000
                        AND PayloadMassKG < 6000
           create pandas df(task 6, database=conn)
Out[15]:
             boosterversion
                F9 FT B1022
                F9 FT B1026
               F9 FT B1021.2
              F9 FT B1031.2
```

Total Number of Successful and Failure Mission Outcomes

 We used wildcard like '%' to filter for WHERE Mission_Outcome was a success or a failure.

```
List the total number of successful and failure mission outcomes
In [16]:
          task 7a = '''
                  SELECT COUNT(MissionOutcome) AS SuccessOutcome
                   FROM SpaceX
                   WHERE MissionOutcome LIKE 'Success%'
          task 7b = '''
                  SELECT COUNT(MissionOutcome) AS FailureOutcome
                   FROM SpaceX
                  WHERE MissionOutcome LIKE 'Failure%'
          print('The total number of successful mission outcome is:')
          display(create pandas df(task 7a, database=conn))
           print()
          print('The total number of failed mission outcome is:')
          create pandas df(task 7b, database=conn)
          The total number of successful mission outcome is:
            successoutcome
          0
                       100
          The total number of failed mission outcome is:
Out[16]:
            failureoutcome
          0
```

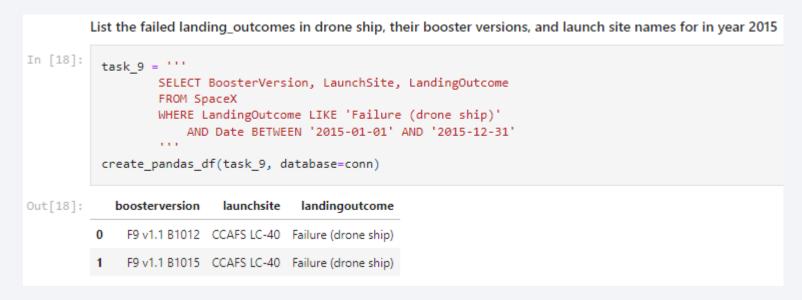

Boosters Carried Maximum Payload

 We determined the booster that have carried the maximum payload using a subquery in the WHERE clause and the MAX() function. List the names of the booster_versions which have carried the maximum payload mass. Use a subquery

Out[17]:	boosterversion		payloadmasskg
	0	F9 B5 B1048.4	15600
	1	F9 B5 B1048.5	15600
	2	F9 B5 B1049.4	15600
	3	F9 B5 B1049.5	15600
	4	F9 B5 B1049.7	15600
	5	F9 B5 B1051.3	15600
	6	F9 B5 B1051.4	15600
	7	F9 B5 B1051.6	15600
	8	F9 B5 B1056.4	15600
	9	F9 B5 B1058.3	15600
	10	F9 B5 B1060.2	15600
	11	F9 B5 B1060.3	15600

2015 Launch Records

 We used a combinations of the WHERE clause, LIKE, AND, and BETWEEN conditions to filter for failed landing outcomes in drone ship, their booster versions, and launch site names for year 2015

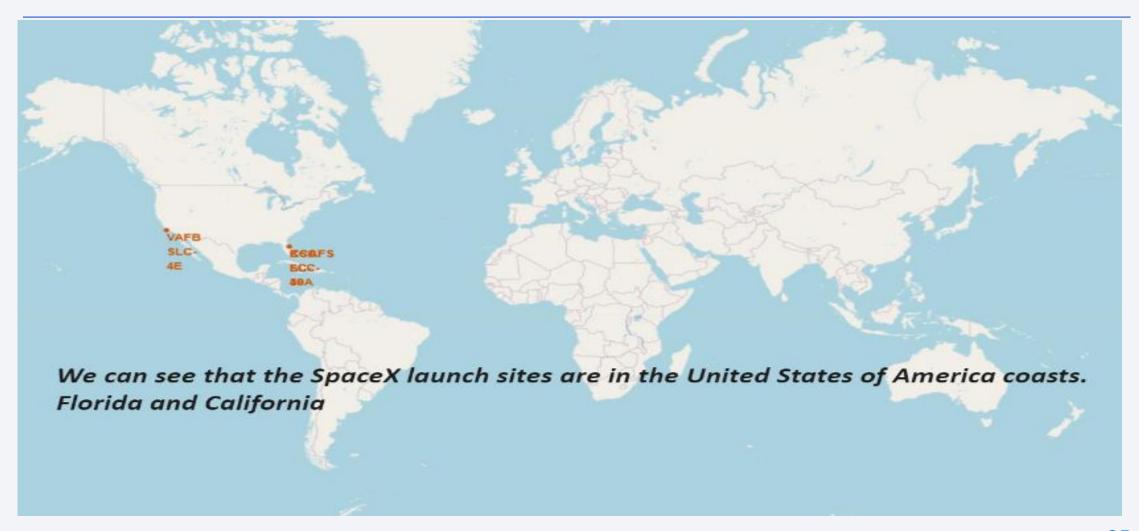

Rank Landing Outcomes Between 2010-06-04 and 2017-03-20

- We selected Landing outcomes and the COUNT of landing outcomes from the data and used the WHERE clause to filter for landing outcomes BETWEEN 2010-06-04 to 2010-03-20.
- We applied the GROUP BY clause to group the landing outcomes and the ORDER BY clause to order the grouped landing outcome in descending order.

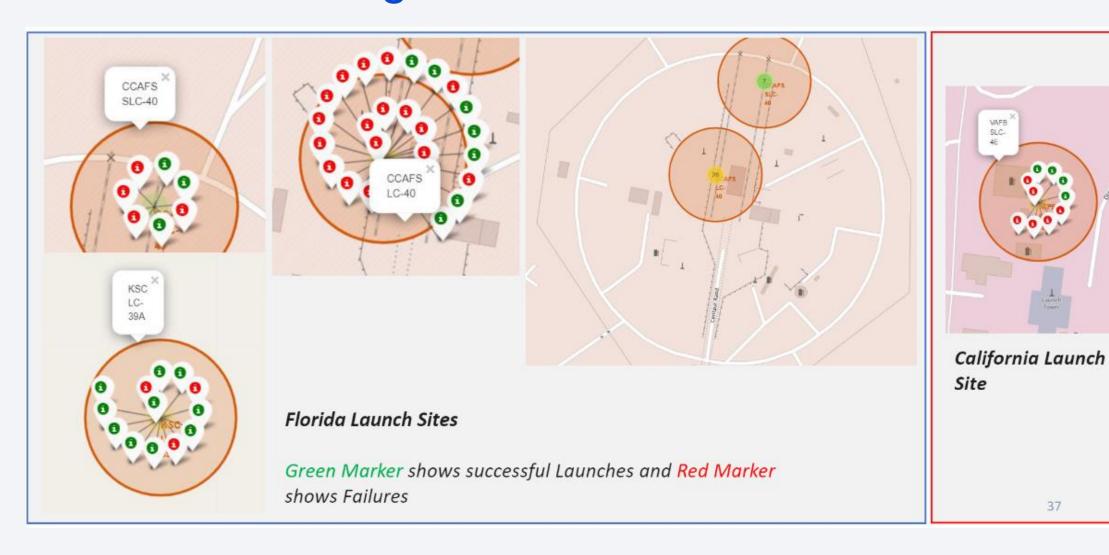

```
Rank the count of landing outcomes (such as Failure (drone ship) or Success (ground pad))
In [19]:
           task 10 = '''
                    SELECT LandingOutcome, COUNT(LandingOutcome)
                    FROM SpaceX
                    WHERE DATE BETWEEN '2010-06-04' AND '2017-03-20'
                    GROUP BY LandingOutcome
                    ORDER BY COUNT(LandingOutcome) DESC
           create pandas df(task 10, database=conn)
Out[19]:
                  landingoutcome count
                       No attempt
                                     10
               Success (drone ship)
                 Failure (drone ship)
              Success (ground pad)
                 Controlled (ocean)
               Uncontrolled (ocean)
           6 Precluded (drone ship)
                 Failure (parachute)
```

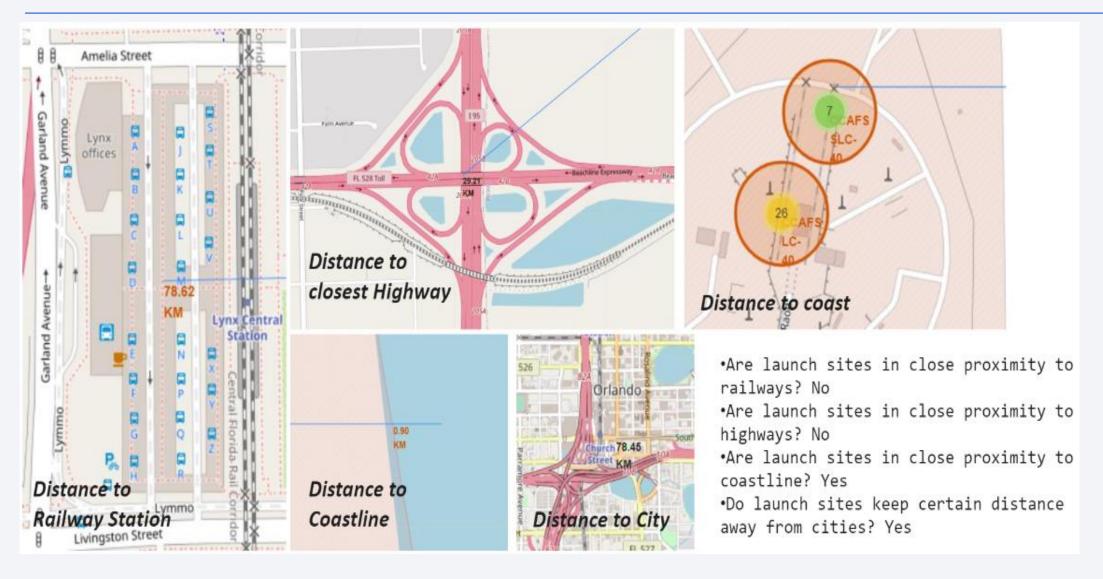

All launch sites global map markers

Markers showing launch sites with color labels

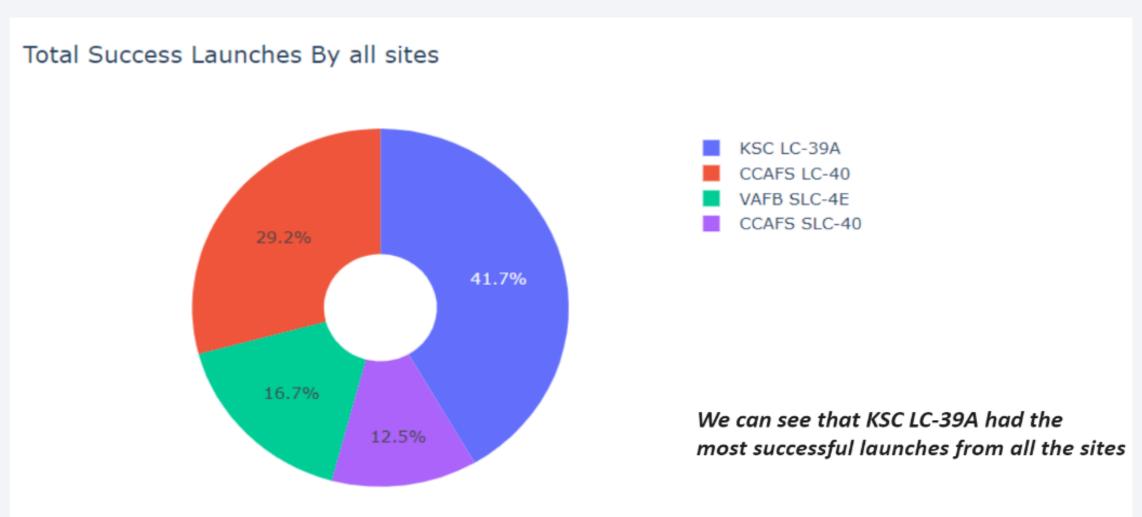

Launch Site distance to landmarks

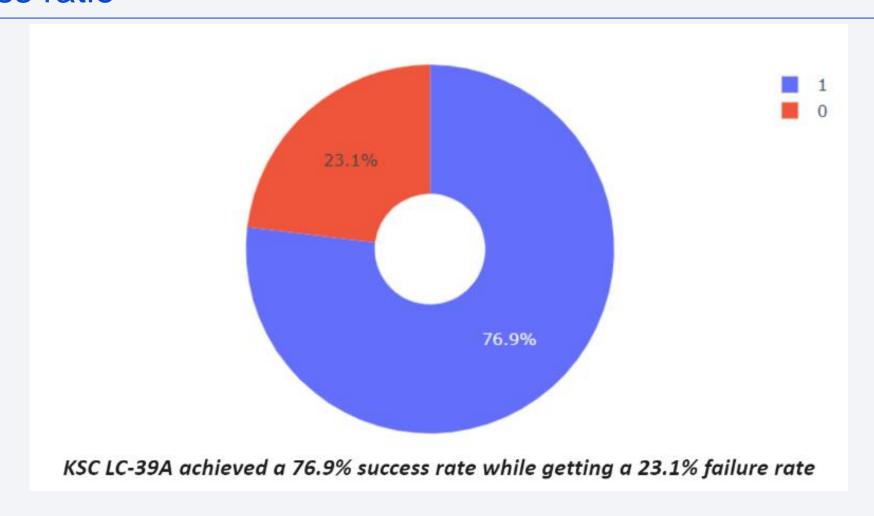

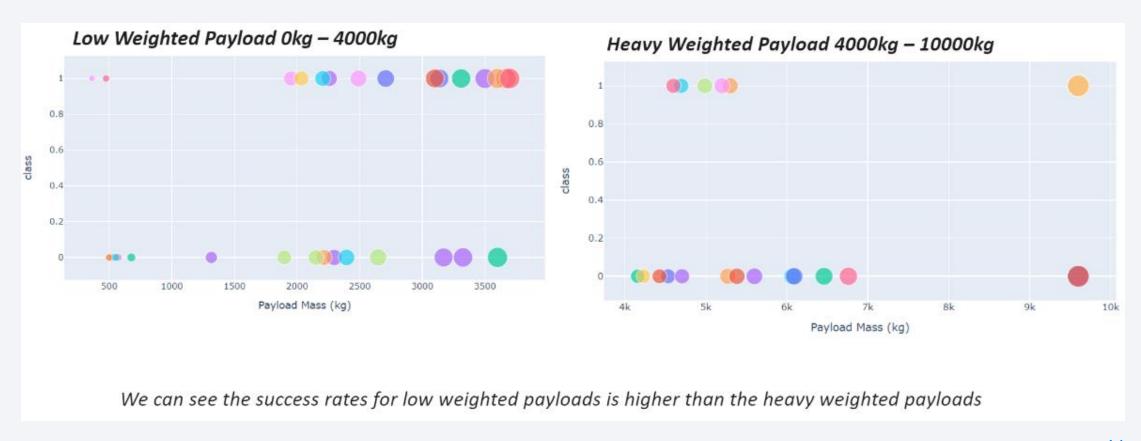

Pie chart showing the success percentage achieved by each launch site

Pie chart showing the Launch site with the highest launch success ratio

Scatter plot of Payload vs Launch Outcome for all sites, with different payload selected in the range slider

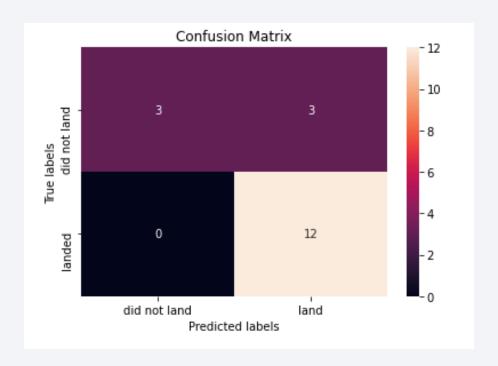

Classification Accuracy

The decision tree classifier is the model with the highest classification accuracy

```
models = {'KNeighbors':knn_cv.best_score_,
              'DecisionTree':tree_cv.best_score_,
              'LogisticRegression':logreg cv.best score ,
               'SupportVector': svm cv.best score }
bestalgorithm = max(models, key=models.get)
print('Best model is', bestalgorithm,'with a score of', models[bestalgorithm])
if bestalgorithm == 'DecisionTree':
    print('Best params is :', tree cv.best params )
if bestalgorithm == 'KNeighbors':
    print('Best params is :', knn cv.best params )
if bestalgorithm == 'LogisticRegression':
    print('Best params is :', logreg_cv.best_params_)
if bestalgorithm == 'SupportVector':
    print('Best params is :', svm cv.best params )
Best model is DecisionTree with a score of 0.8732142857142856
Best params is : {'criterion': 'gini', 'max_depth': 6, 'max_features': 'auto', 'min_samples_leaf': 2, 'min_samples_split': 5, 'splitter': 'random'}
```

Confusion Matrix

 The confusion matrix for the decision tree classifier shows that the classifier can distinguish between the different classes. The major problem is the false positives .i.e., unsuccessful landing marked as successful landing by the classifier.

Conclusions

We can conclude that:

- The higher the number of flights at a launch site, the higher the success rate tends to be at that site.
- The success rate of launches began to rise from 2013 and continued until 2020.
- Orbits such as ES-L1, GEO, HEO, SSO, and VLEO showed the highest success rates.
- Among all launch sites, KSC LC-39A had the highest number of successful launches.
- For this task, the Decision Tree Classifier emerges as the most suitable machine learning algorithm.

Appendix

• Include any relevant assets like Python code snippets, SQL queries, charts, Notebook outputs, or data sets that you may have created during this project
